*Received 24 November 2011; revised 24 February 2012; accepted 27 February 2012*

This study presents variability and concentration of ambient NH<sub>3</sub>, NO and NO<sub>2</sub> along with particulate matter (PM<sub>10</sub>) at urban sites of Chandigarh and Delhi of IGP of India (Dec 2010 - Mar 2011). Concentration of NH<sub>3</sub> was found as follows: Chandigarh, 0.72 - 22.81 (av 5.17 ± 0.92 μg m<sup>-3</sup>); and Delhi, av 8.54 ± 0.72 μg m<sup>-3</sup>. Concentration of ambient NO (av 13.13 ± 1.50 μg m<sup>-3</sup>) and NO<sub>2</sub> (av 5.92 ± 0.38 μg m<sup>-3</sup>) were recorded over Chandigarh. NH<sub>4</sub><sup>+</sup> concentration were found as follows: Chandigarh, 2.60 - 4.39 (av 3.41 ± 0.78 μg m<sup>-3</sup>); and Delhi, 6.61 - 14.6 (av 9.91 ± 3.77 μg m<sup>-3</sup>). Concentration of NH<sub>3</sub> was significantly correlated with NH<sub>4</sub><sup>+</sup> at both of the locations ( $r^2=0.87$  and  $r^2=0.96$ ). NH<sub>3</sub>/NH<sub>4</sub><sup>+</sup> ratios were: Delhi, 0.59 - 1.75 (av 0.86); and Chandigarh, 0.28 - 5.19. A good correlation of SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup> with NH<sub>4</sub><sup>+</sup> over Delhi indicates formation of aerosol. Similar correlations were recorded over Chandigarh.

**Keywords:** Ambient NH<sub>3</sub>, NO, NO<sub>2</sub>, PM<sub>10</sub>, Chemiluminescence method, Meteorological parameters

### Introduction

Ammonia (NH<sub>3</sub>) not only plays important role in acidification and eutrophication of aquatic ecosystems<sup>1</sup> but also neutralizing atmospheric acids (H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub> and HCl) and forms inorganic aerosols<sup>2-4</sup> [(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, NH<sub>4</sub>NO<sub>3</sub> and NH<sub>4</sub>Cl]. Agricultural practices, livestock, transport and industrial activities<sup>2,5</sup> are different anthropogenic sources of atmospheric NH<sub>3</sub>, along with natural sources like forest fire and emission from soil. This study estimated concentration of NH<sub>3</sub>, NO and NO<sub>2</sub> and related particulate matter (PM<sub>10</sub>) over Indo Gangetic Plain (IGP) and correlated NH<sub>3</sub> concentration with related particulates in the formation of secondary aerosol over IGP.

### Experimental Section

Concentrations of ambient NH<sub>3</sub>, NO, NO<sub>2</sub> and PM<sub>10</sub> (NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup>) along with meteorological parameters (temp., RH, wind direction, wind speed etc.) were measured at urban area of Chandigarh and Delhi. NH<sub>3</sub> concentration was measured continuously using NH<sub>3</sub>-analyzer operating based on chemiluminescence

method<sup>3</sup>. PM<sub>10</sub> samples were collected at IMT, Chandigarh and NPL, New Delhi in weekly intervals (day and night basis) to estimate air mass concentration of particulates and water soluble ionic components (NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup>) using Respirable Dust Sampler. Ion concentration of PM<sub>10</sub> was analyzed by Ion Chromatograph with conductivity detector.

### Results and Discussion

Average concentration of ambient NH<sub>3</sub>, NO and NO<sub>2</sub> are summarized (Table 1) alongwith PM<sub>10</sub>, NH<sub>4</sub><sup>+</sup>, SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub><sup>-</sup>. Comparisons of average concentration of ambient NH<sub>3</sub> over various locations<sup>6-11</sup> of IGP India are summarized (Table 2) with present study. Average concentration of NO (Table 1) over Delhi was recorded higher than Chandigarh, may be due to influence of heavy traffic, industries, thermal power plants and rapid urban activities in Delhi. Higher NO concentration from NE direction indicates that major source of NO is road traffic, which is 200 m away from observational site<sup>3</sup>. However, concentration of NO from western direction may be attributed to agricultural field. Average NO<sub>2</sub> concentration over Delhi (Table 1) was recorded one order higher than Chandigarh, may be due to heavy traffic, thermal power plants and industries etc. in Delhi.

<sup>a</sup>Significant at  $P < 0.05$

Ambient NH<sub>3</sub> was significantly negatively correlated with ambient temperature ( $r^2 = -0.81$ ) over Delhi during study (Table 3). Similar observations were also reported<sup>3</sup> during winter at Delhi whereas NH<sub>3</sub> concentration positively correlated with ambient temperature during summer ( $r^2 = 0.79$ ) and autumn ( $r^2 = 0.57$ ). Day time

increase in ambient temperature also attributes to increase in soil temperature which leads to increase soil ammonification and release of NH<sub>3</sub> from soil<sup>3</sup>. Concentration of NH<sub>3</sub> was significantly positively correlated with NO ( $r^2 = 0.96$ ) and NO<sub>2</sub> ( $r^2 = 0.92$ ) over Delhi (Table 3) and similar result was also observed over

Chandigarh. Sharma *et al*<sup>6</sup> have also reported positive correlation of  $\text{NH}_3$  with  $\text{NO}$  and  $\text{NO}_2$  over Delhi.

Positive  $\text{NO}/\text{NH}_3$  ratios over Chandigarh and Delhi indicate influences of  $\text{NO}$  as one of the source of ambient  $\text{NH}_3$ , which also positively correlated with  $\text{SO}_4^{2-}$  ( $r^2 = 0.90$ ) and  $\text{NO}_3^-$  ( $r^2 = 0.91$ ), whereas negatively correlated with ambient temperature ( $r^2 = -0.71$ ) over Delhi (Table 3). Particulate  $\text{NH}_4^+$  was found positively correlated with  $\text{SO}_4^{2-}$  ( $r^2 = 0.91$ ) and  $\text{NO}_3^-$  ( $r^2 = 0.96$ ) over Delhi and similar correlations were observed over Chandigarh (Table 3). Ambient  $\text{NH}_3$  concentration was significantly correlated with  $\text{NH}_4^+$  concentration at both the locations ( $r^2 = 0.87$  and  $r^2 = 0.96$  respectively). Average  $\text{NH}_4^+/\text{SO}_4^{2-}$  and  $\text{NH}_4^+/\text{NO}_3^-$  ratios were computed as 0.40 and 0.38 for Chandigarh respectively, whereas 0.79 and 0.94 for Delhi. A good positive correlation of  $\text{SO}_4^{2-}$  and  $\text{NO}_3^-$  with  $\text{NH}_4^+$  and  $\text{NH}_3$  over both of observational sites over IGP indicates the formation of  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{NH}_4\text{NO}_3$  aerosol<sup>4,5</sup> during winter. Similarly,  $\text{NH}_4^+/\text{SO}_4^{2-}$  and  $\text{NH}_4^+/\text{NO}_3^-$  ratios also support the formation of inorganic/secondary aerosol over the region.

During day time with increasing UV radiation,  $\text{NO}$  rapidly converts into  $\text{NO}_2$  in presence of  $\text{O}^\bullet$  and atmospheric  $\text{NO}_2$  reacts with hydroxyl radical ( $\text{OH}^\bullet$ ) to form nitric acid ( $\text{HNO}_3$ ). However,  $\text{SO}_2$  also reacts with hydroxyl radical ( $\text{OH}^\bullet$ ) to form sulphuric acid ( $\text{H}_2\text{SO}_4$ ). During night time,  $\text{NO}_3^-$  reacts either with  $\text{NO}_2$  to form  $\text{N}_2\text{O}_5$ , which reacts, with  $\text{OH}^\bullet$  to form  $\text{HNO}_3$  or  $\text{NO}_3^-$  directly reacts with water vapor to form  $\text{HNO}_3$ . Reaction of  $\text{HNO}_3$  or  $\text{H}_2\text{SO}_4$  with  $\text{NH}_3$  is reversible and forms  $\text{NH}_4\text{NO}_3$  and  $(\text{NH}_4)_2\text{SO}_4$  respectively. Lower temperature and higher humidity facilitates formation of  $\text{NH}_4^+$  aerosol<sup>6</sup>. A significant relationship ( $r^2 = 0.92$  at Delhi and  $r^2 = 0.90$  at Chandigarh) between  $\text{NH}_3$  and  $\text{NO}_2$  indicates (Table 3) formation of  $\text{HNO}_3$  and simultaneously  $\text{NH}_4\text{NO}_3$  in the atmosphere<sup>6</sup>.

## Conclusions

$\text{NH}_3$  concentration was measured over Chandigarh [ $0.72\text{--}22.81$  (av  $5.17 \pm 0.92 \mu\text{g m}^{-3}$ )] and Delhi (av  $8.54 \pm 0.72 \mu\text{g m}^{-3}$ ), besides concentrations over Chandigarh of ambient  $\text{NO}$  (av  $13.13 \pm 1.50 \mu\text{g m}^{-3}$ ) and  $\text{NO}_2$  (av  $5.92 \pm 0.38 \mu\text{g m}^{-3}$ ).  $\text{NH}_4^+$  concentration were measured over Chandigarh [ $2.60\text{--}4.39$  (av  $3.41 \pm 0.78 \mu\text{g m}^{-3}$ )] and Delhi [ $6.61\text{--}14.6$  (av  $9.91 \pm 3.77 \mu\text{g m}^{-3}$ )]. Concentration of  $\text{NH}_3$  was significantly correlated with  $\text{NH}_4^+$  at both

of the locations ( $r^2 = 0.87$  and  $r^2 = 0.96$ ).  $\text{NH}_3/\text{NH}_4^+$  ratios were calculated over Delhi [ $0.59\text{--}1.75$  (av  $0.86$ )] and Chandigarh ( $0.28\text{--}5.19$ ). A good correlation of  $\text{SO}_4^{2-}$  and  $\text{NO}_3^-$  with  $\text{NH}_4^+$  over Delhi and Chandigarh indicates the formation of aerosol.
