Received 7 December 2010; accepted (revised) 8 November 2012

The oxidation of aryl methyl ketone and heteroaryl methyl ketone to arylglyoxals and heteroaryl glyoxal respectively has been carried out by using the cheap and easily available, non toxic, Lewis acid CuCl₂. The reaction can be performed in air without loss of variety of oxidisable functional group like phenolic OH, hetroaryl ring, aryl substituted methyl, halo, nitro group, etc. 

Keywords: Aryl, heteroaryl, ketone, arylglyoxal, heteroaryl glyoxal, CuCl₂, DMSO

Glyoxal exerts tumor promoting activity on rat glandular stomach carcinogenesis. Aryl glyoxal plays important role in the synthesis of 1-aryl substituted hydantoins, in synthesis of heterocycles like 1,2,4-oxadiazine, 2-imidazoles and synthesis of large rings like [1.1] (2,3) thiopheno (1,1) ferrocenophane-1,7-dione.

A variety of methods have been reported for the oxidative conversion of aryl methyl ketones to arylglyoxal, for example, selenium dioxide (selenious acid), aq. HBr in DMSO and DMSO-I₂/CuO (Ref 8). Similarly, a variety of methods have been reported for the oxidative conversion of aryl methyl ketones to aromatic acids by subsequent oxidation of arylglyoxal using bromine or iodine in a basic media, sodium nitrite-pyridium polyhydrogen fluoride, KOH/DMF, sodium bromite in strong basic conditions, C₆H₅(OCCF₃)₂ (Ref 13), disodium nitroyl pentacyanoferrate and HDNIB-Bu₄NIO₄ (Ref 15). These procedures however, suffer from the following drawbacks: methods need to use either strongly acidic or basic reaction conditions, high cost of the reagents, lengthy procedures, non-compatibility of the other functional groups and low yields, etc.

α-Chloroacetophenone was required for some heterocyclic synthesis. It was thought that chloroacetophenones can be synthesized by using CuCl₂ in DMSO. This reagent had been used earlier by this group to bring about oxidative chlorination of 2'-hydroxychalcones, isoxazoles, naphthalenes and anthracenes. Copper chloride is a mild, cheap and easily available oxidizing reagent. Moreover, it is useful because it is non toxic. Copper chloride has been used in the dehydrogenation of dihydro pyrimidine, for the oxidation of alcohols to the corresponding carbonyl compounds, for the cyclization in Biginelli reaction, for the oxidative cyclization of 2-aminobenzyl alcohol and cyclization of α-hydroxy-β-diketones, nitroaldehyde to aryl glyoxal and aryl glyoxalic acids. Henry and co-workers have performed the Pd catalyzed enantioselective intermolecular chlorohydration of olefins.

After consideration of several possibilities, an alternative preparation of arylglyoxal was sought to avoid some of the drawbacks of the above methods. The conversion of aryl methyl ketones to arylglyoxals through the agency of dimethyl sulfoxide (Me₂SO) and CuCl₂ was found attractive.

Results and Discussion

Earlier, the oxidation of benzoin to benzil could be achieved by using copper chloride in dimethyl sulfoxide (Scheme I). Very surprisingly, the formation of product 2 (Scheme I) could be observed within 20 min with 92% yield. This prompted the study of the effect of copper chloride on active methyl or methylene. To achieve this, acetophenone was selected as a model substrate to study the effect of temperature on the oxidation under neutral conditions in presence of dimethyl sulfoxide as a solvent and 2 moles of copper chloride. It was observed that when the reaction was carried out at 25-60°C there was no change on TLC, indicating no conversion of reactant to product. However, if the temperature was elevated to 70°C a slight change could be observed on TLC indicating the progress of reaction. After workup, a neutral solid product of arylglyoxal was obtained in 25% yield (entry 1 Table I and II). It was further observed that as the temperature increased from 70-80°C the yield of arylglyoxal (entry 1 Table I and II) also increases.
This encouraging result led to the study of a series of other aryl methyl ketones. Gratifyingly, all the reactions proceeded smoothly and afforded the expected products in good yield. An interesting electronic effect seems to exist for aryl methyl ketones oxidation. It was observed that reaction time for electron releasing arens were significantly shorter. The reaction time required for the o-hydroxybenzaldehyde requires longer reaction time which might be attributed to co-ordination of the phenolic OH group with copper chlorides. The substrates with electron withdrawing groups also required longer reaction time and gave higher yield. Increasing the temperature decreases the yield of aryl glyoxal. Addition of base did not improve the yields. It was observed that arylglyoxals were the major product at 80°C (Scheme II) and aromatic acid were the major product at 155°C.

Further, the effect of copper chloride oxidation on acyl substituted heteroaryl derivatives (entry 18,19,20) was studied and it was found that heteroaryl acyl derivatives were smoothly oxidized to heteroaryl glyoxal without loss of the heterocyclic ring.

Active methylene containing derivatives (entry 11, 22) also afforded 1,2-diketone product with moderated yield without loss of any substituent present on the aryl ring.

Most interestingly, the reaction appears to be compatible with oxidizing substituents like aryl substituted methyl, nitro, halo and hydroxyl.

The results of the oxidation of several aryl/heteroaryl methyl ketones derivatives to form aryl/heteroaryl glyoxal under atmospheric conditions with CuCl₂ in dimethyl sulfoxide are summarised in Table II.

### Mechanism

The phenacyl chloride obtained by chlorination of aryl/heteroaryl methyl ketone under neutral conditions can be sequentially oxidized by dimethylsulphoxide to phenyl glyoxal, which can occur via path ‘b’ shown in Scheme III. The mechanism of the oxidation of acetophenone to arylglyoxals may involve chlorination followed by solvolysis of α-chloroacetophenone to α-hydroxyacetophenone. The water required for solvolysis is available in the reaction medium from CuCl₂.2H₂O. The mechanism of oxidation of α-hydroxyacetophenone with cupric(I) acetate in aqueous pyridine has been investigated. This reaction is base dependent and involves the removal of a proton from α-methylene group of copper-ketol complex. Since base was not used in the reaction, the possible mechanism for the oxidation of 2'-hydroxyacetophenone to aryl glyoxal may be excluded. The formation of aryl glyoxal is likely by the pathway suggested by Floyd.

The formation of α-bromoketone from 2-hydroxyacetophenone by using CuBr₂ has been reported. However, the oxidation with DMSO in presence of K₂CO₃ at 120°C was observed as a slow process. Shinara has reported that the peroxide-sulphate Cu²⁺ system yields benzyl alcohol, benzaldehyde, benzoic acid and phenyglyoxylic acid as an intermediate in the oxidation of mandelic acid.

Thus, acetophenone can be oxidized to the corresponding α-keto acid via path ‘a’ and further decarboxylation to aldehydes or oxidative decarboxylation to benzoic acids.

—Contd
oxidation products like 2-hydroxyphenylglyoxalic acid and hemiacetal were not isolated, since, under the reaction conditions aldehyde group could not be oxidized to acid \(^3\).

Experimental results showed that in the proposed mechanism, step b and step c might have comparable reactive rates when the reaction temperature was in the range of 70-80°C. However, if the temperature was elevated to 155°C the oxidation step from a to d might be the fastest reaction in the whole system and the corresponding aromatic acid was the major product.

**Experimental Section**

**Typical experimental procedure:** A mixture of aryl/heteroaryl methyl ketone A (Scheme II) (1 eq) and CuCl\(_2\) (2 eq) in freshly distilled dimethyl sulphoxide was stirred at 80°C for 1-2 hr. Then it was diluted with water, acidified with dil HCl and extracted with ether. The product was purified by recrystallization from ethanol or hexane.

All oxidation products are known compounds and the melting points and spectroscopic data (NMR, IR and MS) of all those compounds matched the physical and spectral data reported in the literature\(^3\). All melting points were determined by open capillary method and are uncorrected. \(^1\)H NMR spectra were recorded on Varian 300 spectrometer with TMS as internal standard. All solvents were distilled directly prior to use. Alcohol, DMSO and CuCl\(_2\) were purchased from Fluka and Merck. The homogeneity of the products and reaction monitoring were accomplished by TLC with silica gel GF\(_{254}\).

2-(2,4-dihydroxyphenyl)-2-oxoacetaldehyde, 11. Yield 38%; m.p.175-78°C; IR(KBr): 1224, 1360, 1690, 1723, 2721, 2825, 3372 cm⁻¹; ¹H NMR(CDCl₃): δ 5.1 (1H,s,D₂O exchangeable,-OH), 5.14 (1H,s,D₂O exchangeable,-OH).
exchangeable, -OH), 6.40-7.47 (3H, m, Ar-H), 9.53(s, 1H, 57.83; H, 4.69. Calcd for C\textsubscript{8}H\textsubscript{13}N: C, 57.73; H, 3.61%.

**Conclusion**

The present investigations are an attempt to point out some of the salient features of the reaction of aromatic ketones with dimethyl sulphoxide in presence of CuCl\textsubscript{2}. This method is compatible with a variety of functional groups. It can tolerate moisture and oxygen from the reaction system. Thus, the present work provides an efficient and inexpensive oxidation procedure for a variety of aryl methyl ketones and heteroaryl methyl ketones. The ease of handling, ready availability, cheapness and non toxicity of the reagent and short reaction duration added to the advantages of this procedure. The conversion of aryl methyl ketones to aryl methyl described here will find wide synthetic applications.
