Mentha piperita (Linn.) leaf extract provides protection against radiation induced chromosomal damage in bone marrow of mice

R M Samarth & Ashok Kumar*

Radiation & Cancer Biology Laboratory, Department of Zoology, University of Rajasthan, Jaipur 302004, India

Received 19 September 2002; revised 27 December 2002

Oral administration of M. piperita (1 g/kg body weight/day) before exposure to gamma radiation was found to be effective in protecting against the chromosomal damage in bone marrow of Swiss albino mice. Animals exposed to 8 Gy gamma radiation showed chromosomal aberrations in the form of chromatid breaks, chromosome breaks, centric rings, dicentrics, exchanges and acentric fragments. There was a significant increase in the frequency of aberrant cells at 6 hr after irradiation. Maximum aberrant cells were observed at 12 hr post-irradiation autopsy time. Further, the frequency of aberrant cells showed decline at late post-irradiation autopsy time. However, in the animals pretreated with Mentha extract, there was a significant decrease in the frequency of aberrant cells as compared to the irradiated control. Also significant increase in percentage of chromatid breaks, chromosome breaks, centric rings, dicentrics, exchanges, acentric fragments, total aberrations and aberrations/damaged cell was observed at 12 hr post-irradiation autopsy time in control animals, whereas Mentha pretreated irradiated animals showed a significant decrease in percentage of such aberrations. A significant decrease in GSH content and increase in LPO level was observed in control animals, whereas Mentha pretreated irradiated animals exhibited a significant increase in GSH content and decrease in LPO level but the values remained below the normal. The radioprotective effect of Mentha was also demonstrated by determining the LD_{50/0} values (DRF=1.78). The results from the present study suggest that Mentha pretreatment provides protection against radiation induced chromosomal damage in bone marrow of Swiss albino mice.

Mentha piperita (Linn.) commonly called as peppermint belonging to the family Labiatae is considered aromatic, stimulant and carminative. It is being used for allaying nausea, flatulence and vomiting. Mentha extract has been shown to have antioxidant and antiperoxidant properties due to the presence of eugenol, caffeic acid, rosmarinic acid and α-tocopherol. Mentha extract and its oil have also been screened for antibacterial and antifungal activities against Pseudomonas solanacearum and Aspergillus niger, Alternaria alternata and Fusarium chlamydosporum, respectively. Vokovic-Gacis and Simc showed that extracts of mint (Mentha) could enhance error-free repair of damage and, hence, could be antimitogenic. Samman et al. reported that Mentha piperita has a chemopreventive effect against shamma (a complex mixture of powdered tobacco, slaked lime, oils, spices and other additives, has been linked to oral cancer in Saudi Arabia) induced carcinogenesis, which could be due to antimitogenic properties. It has been reported that Mentha treatment protects the hematological constituents and serum phosphatases activity in Swiss albino mice against gamma irradiation. Recently, Samarth et al. showed that Mentha piperita (Linn.) leaf extract provides protection against radiation induced alterations in intestinal mucosa of Swiss albino mice. Therefore, the present study has been undertaken to evaluate the radioprotective effect of leaf extract of Mentha piperita Linn. in terms of chromosomal aberrations in bone marrow of Swiss albino mice.

Materials and Methods

Animals — Adult male Swiss albino mice (6-8 weeks old, weighing 25 ± 2 g) maintained in the animal house as an inbred colony (procured from Hamdard University, Delhi) were used. These were maintained on standard mice feed and water ad libitum.

Irradiation — The Cobalt teletherapy unit (ATC-C9) at cancer treatment centre, Radiotherapy Department, SMS Medical College and Hospital, Jaipur was used for irradiation. Unanaesthetised mice restrained in well-ventilated Perspex boxes were exposed to whole-body gamma radiation (8 Gy) at a distance (SSD) of 77.5 cm from the source to deliver the dose rate of 1.59 Gy/min. The dose was calculated as per the physical decay table for Co.
Mentha extract (ME)—Fresh leaves of Mentha piperita Linn. [RUBL-19443], collected locally were air dried, powdered and extracted with double distilled water (DDW) by refluxing for 3 hr (12 hr×3) at 80°C. The extract thus obtained was vacuum evaporated so as to make it in powder form. The extract was redissolved in DDW just before oral administration.

Experimental design—Mice selected from inbred colony were divided into two groups. Animals of one group were administered ME orally (1 g/kg body weight/day) for three consecutive days to serve as experimental, while the other group received DDW (volume equal to ME) to serve as control. On 3rd day, after 30 min of above treatments animals of both the groups were exposed to 8 Gy gamma radiation.

Survival assay—Mice, both control and experimental, exposed whole-body to gamma radiation (4, 6, 8 and 10 Gy) were checked daily for 30 days. The survival percentage of mice up to 30 days of exposure against each radiation dose was used to construct survival-dose-response curves.

Cytogenetic study—Cytogenetic damage in the bone marrow cells was studied by chromosomal aberration analysis. All the animals were injected (i.p.) with 0.025% colchicine and sacrificed 2 hr later by cervical dislocation. Both femurs were dissected out. Metaphase plates were prepared by the air drying method. Bone marrow from the femur was aspirated, washed in saline, treated hypotonically (0.6% sodium citrate), fixed in 3:1 methanol:acetic acid, dried and stained with 4% Giemsa (Sigma, USA). Chromosomal aberrations were scored under a light microscope. A total of 400 metaphase plates were scored per animal. Different types of aberration like chromatid breaks, chromosome breaks, fragments, rings, exchanges and dicentrics were scored. When breaks involved both the chromatids, it was termed "chromosome type" aberration, while "chromatid type" aberration involved only one chromatid. If the deleted portion had no apparent relation to a specific chromosome, it was called a fragment.

Biochemical study—Reduced glutathione (GSH) assay: The hepatic level of reduced glutathione (GSH) was determined by the method as described by Moron et al. GSH content in blood was measured spectrophotometrically using Ellman's reagent (DTNB) as a colouring reagent as per the method described by Beutler et al. The absorbance was read at 412 nm using a UV-VIS Systronics Spectrophotometer.

Lipid peroxidation assay: The lipid peroxidation level in liver and serum was measured using Thiobarbituric Acid Reactive Substances (TBARS) by the method of Ohkawa et al. The absorbance was read at 532 nm.

Statistical analysis—The data were subjected to Student's t test for comparison between the groups. The values are expressed as mean ± SE. Significance level was set at P<0.05, <0.005 and <0.001.

Results
In the present investigation, it was observed that pre-treatment of Mentha enhanced the survival percentage of mice exposed to different doses of gamma radiation. Mentha pre-treatment inhibited mortality completely at 4 and 6 Gy. However, at 8 and 10 Gy, no animal died before day 7, and only 18 and 42% death occurred between day 7 and 10 (Fig. 1). Radiation dose-response curves for mice with or without pretreatment of Mentha are shown in Fig. 2. The LD50/30 for control (irradiation alone) and experimental (Mentha extract+irradiation) animals were computed as 6.48 ± 0.07 and 11.59 ± 0.21 Gy, respectively. On the basis of LD50/30 values, Mentha pretreatment produced a dose reduction factor (DRF) of 1.78.

The present study also reports the radioprotective activity of M. piperita leaf extract in terms of chromosomal aberrations in bone marrow of Swiss albino mice. Animals exposed to 8 Gy gamma radiation showed chromosomal aberrations in the form of chromatid breaks, chromosome breaks, centric rings, dicentrics, exchanges and acentric fragments (Fig. 3). There was a significant increase in the frequency of aberrant cells at 6 hr after irradiation. Maximum aberrant cells were observed at 12 hr post-irradiation. Further, the frequency of aberrant cells showed decline at late post-irradiation autopsy time. However, in the animals pretreated with Mentha extract, there was a significant decrease in the frequency of aberrant cells as compared to the irradiated control (Fig. 4). Also significant increase in percentage of chromatid breaks, chromosome breaks, centric rings, dicentrics, exchanges, acentric fragments, total aberrations and aberrations/damaged cell was observed at 12 hr post-irradiation autopsy time in control animals, whereas Mentha pretreated irradiated animals showed a significant decrease in percentage of such aberrations (Table 1; Figs 5,6).

No significant variation in the hepatic as well as blood GSH content was observed between normal and

Fig. 2.—Survival dose-response curves for determination of LD$_{50/50}$ (Survival data collected for four radiation doses and were calculated by regression analysis.)
Mentha treated animals. However, a significant decrease in GSH was recorded in control animals (irradiation alone). Mentha pretreated irradiated animals showed a significant increase in GSH content (blood as well as liver) with respect to control, but such values remained below normal. An increase in TBARS level in liver and serum was evident in control animals. Although, no significant difference was noticed in such levels in normal and Mentha treated unirradiated animals, but a significant decrease was registered in Mentha pretreated irradiated animals (Figs 7,8).

Discussion

In the present investigation, it has been observed that Mentha pretreated irradiated animals did not show any mortality till day 7 at all radiation doses studied. Thus, Mentha pretreatment showed protection against radiation-induced gastro-intestinal damage; thereby enhanced survival of mice is observed. It was also observed that pretreatment of Mentha extract protects mouse jejunum against the radiation induced reduction in villus height, total cells and mitotic figures/ crypt section. Mentha pretreatment also protects against radiation induced increase in goblet cells/villus section and dead cells/crypt section in jejunum of mice. It has been observed that Mentha pretreated animals showed only 18 and 42 % mortality as compared to 100% mortality in control (irradiation alone) at 8 and 10 Gy respectively. These results indicate that Mentha pretreatment have also provided protection against the hematopoietic death. It was evident from our earlier study that Mentha administration elevated the counts of endogenous spleen colonies and spleen weight significantly. The enhanced survivability observed in Mentha pretreated mice were probably due to accelerated hematopoietic regeneration.

In the present study, the frequency of aberrant cells; chromosome breaks, centric rings, dicentrics, exchanges and acentric fragments significantly increased from 6 hr and reached to maximum at 12 hr in animals exposed to 8 Gy gamma radiation. Exposure to radiation is known to produce a significant increase in the per cent aberrant metaphases as well as in the different aberrations. Damage to the chromosomes is manifested as breaks and fragments, which appear as micronuclei in the rapidly proliferating cells. Enhancement in the frequency of micronuclei and chro-

mosomal aberrations has been reported earlier in the bone marrow of irradiated mice.\cite{18,19}

Ionizing radiation is a highly efficient cytotoxic agent. An X-ray dose of 1.5 Gy produces approximately $10^6 M$ radicals in cells. DNA is the critical target for cell killing by ionizing radiation, and there is growing evidence that the particular damage responsible are DNA double-strand lesions, such as DSB. While damage to other biological molecules does occur and is potentially cytotoxic. It has been recognized that structural aberrations can be induced in chromosomes by radiation at any stage of their mitotic cycle. When cells are irradiated just as they enter division, there is apparently some change in the surface properties of the chromosomes, which cause them to adhere to each other when they happen to

touch. This stickiness has been attributed to a partial dissociation of the nucleoproteins and an alteration in their pattern of organization. Natarajan et al. and Bryant suggested that double strand breaks (dsb) are mainly responsible for the formation of chromosomal aberrations.

It has been observed that pretreatment with Mentha extract was effective in protecting the chromosomal damage against irradiation, as is evidenced by a significantly lower levels of chromatid breaks, chromosome breaks, centric rings, dicentrics, exchanges, fragments and total aberrations. It is well known that free radicals generated during radiolysis of water play the most significant role in the indirect biological damage induced by ionizing radiation. The GSH/GST detoxification system is an important part of cellular defense against a large array of injurious agents. GSH offers protection against oxygen derived free radicals and cellular lethality following exposure to ionizing radiation. Under normal conditions the inherent defense system including glutathione and the antioxidant enzymes, protects against the oxidative damage. GSH is a versatile protector and executes its radioprotective function through free radical scavenging, restoration of the damaged molecule by hydrogen donation, reduction of peroxides and maintenance of protein thiols in the reduced state.

The present study demonstrates a significant reduction in liver and blood GSH, following exposure. This could be due to the enhanced utilization of the antioxidant system as an attempt to detoxify the free radicals generated by radiation. Oral administration of Mentha extract did not significantly influence the endogenous GSH level either in liver or blood, but its presence while radiation exposure protects the endogenous GSH depletion due to irradiation. The lower depletion of liver and blood GSH in the Mentha pretreated irradiated animals could be due to the higher availability of GSH, which increases the ability to cope up with the free radicals produced by radiation. The increased GSH level suggests that protection by Mentha may be mediated through the modulation of cellular antioxidant levels. Ochi have reported that chromosomal aberrations were repaired only in GSH positive cells. Thus it is possible that the elevated levels of GSH in Mentha pretreated irradiated animals may be able to enhance the repair of dsb, hence lower frequency of chromosomal aberrations was evident in this group.

The basic effect of radiation on cellular membranes is believed to be the peroxidation of membrane lipids. Radiolytic products, including hydroxyl and hydroperoxyl radicals can initiate lipid peroxidation. In the present study, it was observed that, although Mentha treatment did not significantly alter the lipid peroxidation level in unirradiated animals, it significantly lowered the radiation induced lipid peroxidation in terms of malondialdehyde. Inhibition of lipid peroxidation in biomembranes can be caused by antioxidants. It has been shown that more α-tocopherol is needed in the membranes to protect polyunsaturated fatty acids (PUFA) against radiation induced lipid peroxidation when low dose-rates are applied. Several mechanisms, including a potent antioxidant activity, immune response and enhanced recovery of bone marrow have been suggested for radioprotection by vitamin E. In the present study, it was observed that Mentha pretreated irradiated animals exhibited a significant increase in GSH and decrease in LPO.
level. Mentha extract has been shown to have antioxidant and antiperoxidant properties due to the presence of eugenol, caffeic acid, rosmarinic acid and α-tocopherol. Vokovic-Gacis and Simic showed that extracts of mint (Mentha) could enhance error-free repair of damage and, hence, could be antimitogenic. Samman et al. reported that Mentha piperita has a chemopreventive effect against shamma induced carcinogenesis, which could be due to antimutagenic properties. A combination of antioxidative and antimitogenic activities via modulation of DNA repair processes may be held responsible for the radioprotective effects of Mentha piperita (Linn.) leaf extract.
