Received 6 July 1999; revised 1 March 2000

Ginger (Z. officinale; 1% w/w) significantly lowered lipid peroxidation by maintaining the activities of the antioxidant enzymes—superoxide dismutase, catalase and glutathione peroxidase in rats. The blood glutathione content was significantly increased in ginger fed rats. Similar effects were also observed after natural antioxidant ascorbic acid (100 mg/kg, body wt) treatment. The results indicate that ginger is comparatively as effective as ascorbic acid as an antioxidant.

Detrimental effects caused by free radicals occur as a consequence of an imbalance between formation and inactivation of these species. Oxidative damage may be involved in the pathogenesis of major diseases such as cancer, atherosclerosis and certain neurological disorders. The relevance of free radicals/reactive oxygen species (ROS) in tissue damage and carcinogenesis has been reported. Inactivation and removal of ROS depend on reactions involving the antioxidative defence system. Hence, it is important to identify natural antioxidative agents present in diets consumed by the human population.

Ginger rhizome (Zingiber officinale Rosc) commonly known as ginger, is consumed world wide as a spice and flavoring agent. In India, ginger is used extensively in both vegetarian and non-vegetarian diets. Limited in vitro studies have shown that water and organic solvent extracts of ginger possess antioxidant properties. Oral consumption of ginger (dried, powdered) has been shown to result in relief of pain and swelling in patients with rheumatoid arthritis, osteoarthritis or muscular discomfort. Ginger oil has been found to be an inhibitor of both cyclooxygenase and lipooxygenase activities. Recently, Sharma et al. have suggested that ginger oil possesses antiinflammatory properties. A combination of ginger and garlic has been reported to produce hypoglycemic and hypolipidemic effects. In a recent study dietary ginger protected the tissues from oxidative stress induced by organophosphate pesticide (malathion) in rats. In view of the above, it is of much interest and practical importance to study influence of long term dietary ginger on antioxidative potential. Hence, effects of dietary ginger have been assessed on (a) lipid peroxidation; (b) antioxidant scavengers-superoxide dismutase (SOD) and catalase (CAT); and (c) glutathione linked enzyme system in blood. Simultaneously, antioxidative properties of ginger in rats were compared with ascorbic acid-a natural antioxidant.

Animals and diet—Male albino rats (Wistar strain) weighing 200-250 g were placed in individual raised bottom, galvanized wire cages and kept under standard laboratory conditions of light-dark cycle (12-12 hr) and temperature (25 °±2 °C). They were provided with a nutritionally adequate standard laboratory diet. The experimental diet (1% ginger) was prepared as follows. Fresh ginger was purchased from the local market, peeled, washed, coarsely minced air dried and pulverized with a blender to fine powder. This was added w/w to already pulverized feed and thoroughly mixed so as to get a diet containing 1% ginger. The rats were randomly divided into 3 groups of 10 animals each and treated for 4 weeks as follows:

- **Group I, Control:** rats fed on normal diet
- **Group II, Rats fed on 1% ginger diet**
- **Group III, Rats fed on normal diet and treated with ascorbic acid (100 mg/kg/d) orally by gastric tube at 0900 hrs throughout the experimental period.**

Samples—After overnight fasting, animals were sacrificed by decapitation and heparinized blood samples were collected and processed for isolation of erythrocytes. Whole blood samples were also collected and sera separated for various biochemical investigations. Hb concentration was determined spectrophotometrically at 540 nm using Drabkin’s reagent. Erythrocytes were isolated and haemolyzed. Protein content of haemolysate was estimated as per Lowry et al.

Biochemical estimations—Lipid peroxidation level in serum was measured as thiobarbituric acid reactive substances (TBARS) according to the method described by Satoh. Superoxide dismutase (SOD, E.C. 1.15.1.1) activity in erythrocytes was determined. Catalase (CAT, E.C. 1.11.1.6) activity was measured in Tsuchihasi extract of red cell haemolysate. Total glutathione (GSH) content in blood was measured by the method of Tietze. Glutathione reductase (GR, E.C. 1.6.4.2) activity in plasma and total activity of glutathione peroxidase (GPx, E.C. 1.11.1.9) in red cell haemolysate were determined. Serum glutathione-S-transferase (GST, E.C. 2.5.1.18) activity was measured spectrophotometrically by the method of Habig et al. using I-chloro, 2,4-dinitrobenzene as substrate. The values are expressed as mean±SD. The data were analysed using one way ANOVA followed by Tukey’s test for intergroup comparison.

Ascorbic acid is a potent antioxidant which acts directly on oxygen free radicals (OFR) as well as through interactions with vitamin E. However, ascorbic acid per se, did not have any effect on SOD activity in the present study (Table 1) which is in agreement with earlier reports. Similar effects for dietary ginger on SOD were observed (Table 1). Both CAT and GPx activities (Table 1) remained unaltered in ginger fed and ascorbic acid treated animals indicating that production of H$_2$O$_2$ is not high enough to warrant any increase in these enzymes and they are maintained at normal levels. The activities of GST and GR did not show any alteration in ginger and ascorbic acid treated groups (Table 1).

Lipid peroxidation plays a crucial role in inflammation, cancer and cardiac diseases. The present results showed that dietary feeding of ginger significantly lowers lipid peroxidation, similar to ascorbic acid. Curcumin, a major component of turmeric can lower lipid peroxidation. Curcumin and zingerone, compounds abundant in ascorbic acid and zingerone components present in ginger.

Glutathione is the first line of defense against prooxidant stress and GSH was elevated after ginger feeding. GSH system may have the ability to manage oxidative stress with adaptational changes in enzymes regulating GSH metabolism. However, the mechanism by which ginger provides an environment for the enhanced level of GSH is yet to be ascertained. The results of the present study suggest that ginger exerts antioxidative effect by decreasing lipid peroxidation, increasing GSH content and maintaining normal levels of antioxidant enzymes (SOD, CAT, GPx and GR). Scavenging of superoxide radicals by some spice principles have been documented.

Present study in rats given normal diet along with ginger prevented the formation of unwanted free radicals, maintained the integrity of erythrocytes and

the effects were similar to that of ascorbic acid, a known natural antioxidant. Hence ginger may be taken regularly in the normal diet for therapeutic purposes. Furthermore, similar studies on antioxidant status during a free radical challenge can be used as an index of protection against the development of lipid peroxidation in experimental animals\(^\text{16,17}\).
