Received 27 December 1988; revised and accepted 15 May 1989

The kinetics of solvolysis of cis-(chloro)(cyclohexylamine)bis(ethylenediamine)cobalt(III) ion have been investigated in acetone + water (0-50 wt% acetone) in the temperature range of 35-50°C. The plots of log $k_{obs}$ versus the reciprocal of the bulk dielectric constant ($D_s^{-1}$) of the mixed solvent and log $k_{obs}$ versus solvent Y-Bud' parameter were nonlinear. The plots of log $k_{obs}$ versus $X_{org}$ ($X_{org} =$ mol fraction of acetone) at 35°C to 50°C are strikingly linear with the common gradient $= -3.14±0.10$. These facts are in keeping with the importance of the solvent structural effects and the lack of appreciable preferential solvation of the substrate under the conditions of rate measurements. It is striking to note that unlike for the alcohol-water solvent systems and a variety of cobalt(III) substrates, $\Delta H^*$ (and $\Delta S^*$) solvent composition profile in the present case, displaying a weak maximum at $X_{Me_2CO} = 0.01$ is little sensitive to the medium beyond $X_{Me_2CO} = 0.05$.

In a preceding paper$^2$ the rate and activation parameters for the solvolysis of cis-[Co(en)$_2$(ChXNH$_2$)Cl]$^2+$ (ChXNH$_2$ = cyclohexylamine) in methanol + water, propan-2-ol + water, ethylene glycol + water (0-80 wt% of alcohols) and t-butanol + water (0-50 wt% of t-butanol) were reported. Title investigation is an extension of our earlier work$^2$.

Experimental

Cis-(chloro)(cyclohexylamine) bis(ethylenediamine)cobalt(III) diperchlorate was prepared and its purity checked as described earlier$^3$. Acetone (AR, Glaxo, India, 99.5% pure) was dried over molecular sieve (4A), distilled and the middle fraction was collected. Solvent mixtures were prepared by wt% basis. Spectral measurements were made with a Hitachi model 200-20 UV-visible spectrophotometer.

Kinetic measurements

The kinetics of solvolysis of the complex was followed by potentiometric titration of the liberated chloride. The experimental procedure for rate measurement and calculation of the pseudo-first order constants from replicate runs were the same as described earlier$^3$.

Results and discussion

Successive spectral scans for the reaction mixture at 45°C in 50 wt% of acetone + water medium exhibited isosbestic point at 396 nm, which remained unchanged even after a long time interval, ruling out the possibility of any other secondary reaction. The primary solvolytic reaction may be represented by Eq. (1).

$$cis-[Co(en)$_2$(ChXNH$_2$)Cl]$^2+ \xrightarrow{k_{obs}} H_2O$$  
$$cis-[Co(en)$_2$(ChXNH$_2$)H$_2$O]$^3+ + Cl^- \ldots (1)$$

The rate of acid hydrolysis of the title complex is insensitive to changes in [H$^+$] in the range of 0.0010-0.050 mol dm$^{-3}$. Hence [HClO$_4$]$_{ref}$ was fixed at 0.0010 mol dm$^{-3}$ for all the runs. The rate data are presented in Table 1, while the activation parameters, calculated by a weighted least squares procedure, are collected in Table 2.

Variation of rate constant ($k_{obs}$) with solvent composition

The $k_{obs}$ decreased with increase in acetone content of the solvent mixture. The variation of log $k_{obs}$ with $D_i^{-1}$ where $D_i^{-1} =$ reciprocal of the bulk dielectric constant$^4$ is non-linear at all temperatures which may be attributed to (i) failure of both the point charge model of the complex ion and the dielectric continuum model of the reaction medium, and (ii) non-linear variation of the non-electrostatic component of the relative transfer free energy term [$\Delta G_{i,s}^r - \Delta G_{i,s}^{r,s}l_{k_{obs}}$] with the solvent composition due to the solvent structural effects (see later).

The plot of log $k_{obs}$ (25°C) versus $Y_{BuCl}$, the Grunwald Winstein solvent ionising parameter$^5$, is S-shaped (see Fig. 1) indicating that the reference,

Fig. 1—6 + log(\(k_{\text{obs}}\)/s^{-1}) versus \(Y_{t-BuCl}\) plot at 25\(^{\circ}\)C

Fig. 2—6 + log(\(k_{\text{obs}}\)/s^{-1}) versus \(X_{\text{org}}\) plots at different temperatures (1) 35\(^{\circ}\)C, (2) 40\(^{\circ}\)C, (3) 45\(^{\circ}\)C and (4) 50\(^{\circ}\)C

to the free energy of transfer of the transition state \([\Delta G_{t}(t.s.)_{s-w}]\) and the initial state \([\Delta G_{t}(i.s.)_{s-w}]\) as given by Eq. (2)

\[
\log k_{\text{obs}} = \log k_{\text{obs}}^\text{w} - \left(\frac{1}{2.303 RT}\right)[\Delta G_t(t.s.)_{s-w}] - [\Delta G_t(i.s.)_{s-w}] \quad \ldots (2)
\]

substrate (i.e. \(t-BuCl\)) and the title complex undergo solute-solvent interaction differently although from the mechanistic grounds the solvolytic process of both these substrates may be very much alike (i.e. dissociative interchange).

The familiar dissociative interchange mechanism, \((\text{i})^9\), in which the Co-Cl bond is believed to be stretched to the maximum limit of cleavage in the transition state, may be depicted as in Scheme 1 of ref. 7 for which the rate constants are related
log \( k_{\text{obs}}^{\text{water}} \) and \( X_{\text{org}} \) is expected if the relative transfer free energy function varies linearly with \( X_{\text{org}} \). As per expectation the plots of log \( k_{\text{obs}}^{\text{water}} \) versus \( X_{\text{Me}_{2}\text{CO}} \) (see Fig. 2) are linear with gradients = \(-3.14 \pm 0.10\) at 35°C to 50°C. Hence the effect of preferential solvation seems to be insignificant. Furthermore, such linear plots reflect that solvation of the initial state and transition state is grossly controlled by the acidity and basicity of the mixed solvent which also vary linearly with the mol fraction of the cosolvent. In the dissociative interchange transition state the leaving group is virtually dissociated from the cobalt (III) centre. Hence the additivity principle may be assumed to be valid for \( \Delta G^{\text{t.s.}} \) and in the t.s. the respective charges of the leaving groups are fully developed. We can then write

\[
[\Delta G^{\text{t.s.}}]_{\text{s-w}} = [\Delta G^{(C^{3+})}]_{\text{s-w}} + [\Delta G^{(\text{Cl}^{-})}]_{\text{s-w}} \quad \ldots \quad (3)
\]

where \([\Delta G^{(C^{3+})}]_{\text{s-w}}\) denotes the transfer free energy of the dissociative transition state, \((C^{3+}) = [(\text{cis-}[\text{Co}((\text{en})_{2}\text{ChXNH}_{2}]^{3+}])^{+}]\). The values of the relative transfer free energy term \([\Delta G^{(C^{3+})} - \Delta G^{(\text{i.s.})}]_{\text{s-w}}\) at various \(X_{\text{Me}_{2}\text{CO}}\) at 25°C were calculated using Eq. (4) obtained by combining Eqs (2) and (3) and the calculated values of

\[
[\Delta G^{(C^{3+})} - \Delta G^{(\text{i.s.})}]_{\text{s-w}} = 2.303RT \log\left(\frac{k^{\text{water}}}{k^{\text{obs}}}ight) - [\Delta G^{(\text{Cl}^{-})}]_{\text{s-w}} \quad \ldots \quad (4)
\]

\([\Delta G^{(\text{Cl}^{-})}]_{\text{s-w}}\) reported by Wells. The values of \([\Delta G^{(C^{3+})} - \Delta G^{(\text{i.s.})}]_{\text{s-w}}\) were negative at all compositions and decreased non-linearly with increase in \(X_{\text{Me}_{2}\text{CO}}\) tending to reach asymptotic limit (Fig. 3). This reflects a strong propensity of the tripositive cobalt (III) species (C³⁺) to solvation, and relative to fully aqueous medium such a species is stabilized in the mixed solvent to a greater extent than the corresponding dipositive initial state. However, the negative values of \([\Delta G^{(C^{3+})} - \Delta G^{(\text{i.s.})}]_{\text{s-w}}\) do not lead to the rate enhancement since the positive values of \([\Delta G^{(\text{Cl}^{-})}]_{\text{s-w}}\) (=1.92 to 13.8 kJ mol⁻¹ for 0.016 ≤ \(X_{\text{Me}_{2}\text{CO}}\) ≤ 0.236 at 25°C) tip the balance in favour of rate retardation with increase in \(X_{\text{Me}_{2}\text{CO}}\).

Variation of activation parameters with solvent compositions

Plots of \(\Delta H^*\) and \(\Delta S^*\) versus \(X_{\text{Me}_{2}\text{CO}}\) displayed a weak maximum around \(X_{\text{Me}_{2}\text{CO}}\approx 0.01\) (Fig. 4), in contrast to the well-defined extrema observed for this substrate in methanol + water, propan-2-ol + water, ethyleneglycol + water, t-butanol + water media. Also it is worth noting that \(\Delta H^*\) (or \(\Delta S^*\)) versus \(X_{\text{Me}_{2}\text{CO}}\) plot for acetonitrile + water media for the cyclohexylamine bis(ethylenediamine) complex is very much different from that of the cis-[(en)₂Co(2-aminothiazole)Br]²⁺ in acetonitrile + water media for which multiple maxima and minima are observed. This is suggestive of the fact that the non-labile ligand envelope of the substrate has a significant role in modulating at least the solvational components of these activation parameters (\(\Delta X^*_\text{overall} = \Delta X^*_R + \Delta X^*_S\) where \(X = \text{H, S}\) and the subscripts \(R\) and \(S\) denote the reaction and solvational components respectively). The observed variation of \(\Delta H^*\) and \(\Delta S^*\) with \(X_{\text{Me}_{2}\text{CO}}\) may be compared with that of \(\text{trans}[(\text{en})\text{Co}^{\text{II}}\text{Cl}]^+\) in ethanomitrile + water media reported by Wells et al. The \(\Delta H^*\) (and \(\Delta S^*\))-composition profile indicat-
ed that the solvent structural promotion is significant around $X_{\text{Me}2CO} = 0.01$. However, $\Delta G^\circ$ increased linearly with $X_{\text{org}}$ over the entire composition range. Evidently the rate enhancing effect due to decrease in $\Delta H^\circ$ is compensated by large negative values of $\Delta S^\circ$. To a large extent the effects of $\Delta H^\circ$ and $\Delta S^\circ$ on the rate are mutually compensatory (see Fig. 4). The large negative values of $\Delta S^\circ$, being consistent with the stereoretentive solvolysis, corroborate the fact that the transition state is much more solvated than the initial state. This might be a consequence of the hydrophobic association between the molecules of the organic cosolvent and the hydrophobic ligand moiety of the cobalt (III) substrate. The validity of the compensation law ($\Delta H^\circ = \alpha + \beta \Delta S^\circ$; $\alpha = 105.5$ kJ mol$^{-1}$, $\beta = 288.5$ K) irrespective of the nature of the organic solvent and the solvent composition is in keeping with the fact that perturbations in the reaction zone and the solvent network remain proportional to each other with increase in $X_{\text{org}}$.
