Chlorination of aniline by dichloramine-T in 1:1 aqueous acetic acid medium, in the presence and absence of acetate ions is first order in [oxidant], nearly first order in [aniline], inverse fractional order in [H$^+$] and fractional order in added [acetate ion] at constant ionic strength. Effects of added reaction products and variations in ionic strength and solvent composition of the reaction medium have also been investigated. Mechanisms consistent with the observed results are discussed and the related rate laws deduced.

The present investigation is a part of our mechanistic studies with positive halogens in general and N,N-dihalosulphonamides in particular. We report herein the kinetics of chlorination of aniline by N,N-dichloro-p-toluenesulphonamide (dichloramine-T, OCT) in 1:1 (v/v) water-acetic acid medium under varying conditions.

Materials and Methods
N,N-Dichloro-p-toluenesulphonamide (dichloramine-T or OCT) was prepared in the laboratory and its purity checked by elemental analyses, spectral data (IR and PMR) and iodometric estimation of active halogen present in it. Stock solution (0.1 mol dm$^{-3}$) of OCT was prepared in purified dry acetic acid and standardised by iodometric method.

Aniline was redistilled before use. All other reagents used were of AR grade. The ionic strength of the medium was kept at 0.2 or 0.4 mol dm$^{-3}$ by adding concentrated aqueous solution of sodium acetate or sodium perchlorate.

Kinetic measurements
The kinetic studies were carried out in 50% (v/v) aqueous acetic acid under pseudo-first order conditions ([aniline] $>$ [CAT], 5-10 times). The reactions were initiated by quick addition of a measured quantity of OCT solution in acetic acid, thermally equilibrated at a desired temperature, to a mixture containing known amounts of aniline, sodium acetate (and sodium perchlorate), HClO$_4$, acetic acid and water [to maintain 50% (v/v) solvent composition], pre-equilibrated at the same temperature. The progress of the reaction was monitored for nearly two half-lives by iodometric method. The pseudo-first order rate constants computed by the method of least squares were reproducible within ±4%.

Stoichiometry
The stoichiometry of DCT-aniline reaction was determined by equilibrating (at 303 K) reaction mixtures containing slight excess of DCT and different [HClO$_4$] in solvent mixtures of different compositions, both in the presence and absence of sodium acetate. Analysis of reaction mixtures showed that two moles of aniline reacted with one mole of DCT in accordance with Eq. (1).

$$2C_6H_5NH_2 + RNCl_2 \rightarrow 2C_6H_4ClNH_2 + RNH_2$$ (1)

where R = CH$_3$C$_6$H$_4$SO$_2$.

Results
Plots of log [DCT] versus time were linear for two half-lives (Fig. 1). Pseudo-first order rate constants ($k_{obs}$) remained unaffected by changes in [DCT]$_0$, both in the presence and absence of NaOAc (Table 1), establishing first order dependence in [DCT]$_0$. Rate increased with increase in [aniline] with almost first order dependence in [aniline] both in the presence and absence of NaOAc. Plot of $k_{obs}$ versus [aniline] was linear without any intercept. Variation in [H$^+$] by adding HClO$_4$ decreased the rate of oxidation both in the presence of NaOAc and in the absence (twenty-fold variation in HClO$_4$ changed pH by 0.5 unit only) (Table 2). Plot of log $k_{obs}$ versus log [H$^+$] showed inverse fractional order dependence in [H$^+$] both in the absence and presence of NaOAc. Increase in ionic strength of the medium by adding NaClO$_4$ solution had negligible effect. Further the rate increased with increase in [NaOAc] at constant ionic strength. Plot of $k_{obs}$ versus [NaOAc] was linear with a finite intercept, indicating participation of acetate ion in the reaction (Fig. 2). Addition of the reaction product, p-toluenesulphonamide had no ef-

Discussion

Mechanism of chlorination

The probable reactive oxidant species in aqueous acetic acid medium are RNCl₂, (RNCl₂H)⁺ and...
CH₃COOCl. First order dependence in [DCT], nearly first order dependence in [aniline], fractional order in [acetate] and inverse fractional order dependence in [H⁺] may be explained by a two-pathway mechanism, one via the formation of acyl hypochlorite intermediate (Eq. 2) and the other through the direct pathway (Eq. 3). This is supported by the fact that the plots of $k_{obs}$ versus [acetate], and $k_{obs}$ versus $1/\left[H^+\right]$ are linear with finite intercepts (Fig. 2) and the corresponding reciprocal plots are nonlinear (figure not shown), attaining the limiting values. Increase in rate with increase in [acetate] at constant ionic strength also indicates participation of CH₃COO⁻ in the reaction.

$$RNCl_2 + CH_3COO^- + S \rightarrow k_1 \text{ Products} \quad \ldots (2)$$

and

$$RNCl_2 + S \rightarrow \text{Products} \quad \ldots (3)$$

(S refers to substrate)

Related rate laws are given by Eqs (4) and (5).  

$$- \frac{d[DCT]}{dt} = k_1[DCT][CH_3COO^-] + k_2[DCT][S] \quad \ldots (4)$$

$$k_{obs} = k_1[S][CH_3COO^-] + k_2[S] \quad \ldots (5)$$

Substituting $[CH_3COO^-] = K_1[CH_3COOH]/[H^+]$ we get

$$k_{obs} = \frac{K_1 k_1[S][CH_3COOH]}{[H^+]} + k_2[S] \quad \ldots (6)$$

Rate law (6) envisages that the plot of $k_{obs}$ versus [S] should be linear with almost no intercept on the ordinate. This is actually found to be the case (figure not shown). Further, as already pointed out, plots of $k_{obs}$ versus $[CH_3COO^-]$ and $k_{obs}$ versus $1/[H^+]$ are also linear with intercepts on the ordinate (Fig. 2). Values of the constants $k_1$ and $k_2$ have been calculated from the slopes and intercepts of the above plots respectively. These constants are used to predict the rate constants at varying [S]. Predicted values compare very well with the experimental rate constants (Table 4).

The reaction between aniline and DCT via N-chloro intermediate is supported by the observation that there is no reaction between DCT and acetanilide (containing an electron-withdrawing N-acetyl group) under identical conditions and the introduction of NO$_2$ group in benzene ring decreases the rate by about 20 times. Further the rate of chlorination of $o$-chloroaniline is about one-third that for aniline (Table 5). While the substituent at the $p$-position decreases the rate by about 20%. Replacement of one of the hydrogens of $-NH_2$ group by methyl group increases the rate to almost double whereas replacement of both the hydrogen atoms decreases the rate. Electron-releasing substituents (such as Me) at the para- and meta-positions generally increase the rates while electron-withdrawing substituents decrease the rate (Table 5).

Large negative entropies of activation and high positive free energy of activation (Table 3) suggest the role of bond breaking in attaining the activated state.

The observed negative dielectric effect is in conformity with the Amis' concept for dipolar molecule-dipolar molecule and dipolar molecule-negative ion interactions and the proposed mechanisms.
