Kinetics and mechanism of oxidation of thiocyanate ion (NCS⁻) by chloramine-B (CAB) and bromamine-B (BAB) have been studied in the alkaline medium over a wide range of [NCS⁻] and [OH⁻]. The order in [CAB] is unity over the entire range of [NCS⁻] (0.01-0.5 mol dm⁻³), fractional in [NCS⁻] and inverse fractional in [OH⁻]. The order in [BAB] is unity, zero in [NCS⁻] and fractional in [OH⁻]. Effects of added reaction products and variations in ionic strength and dielectric constant of the reaction medium on the rate have also been investigated. Mechanisms in conformity with the observed kinetics have been proposed and the corresponding rate laws deduced. The activation parameters have been computed from the rate constants of the rate-determining steps.

The kinetics of oxidation of NCS⁻ by hydrogen peroxide¹, aqueous iodine², Cr(VI) and V(V)³, Bi(V)⁴ and chloramine-T⁵,⁶ are reported in literature. As a part of our kinetic investigations employing N-halogeno-N-metallo reagents as oxidants¹⁻⁹ we report herein the results of investigations on the oxidation of thiocyanate ion by chloramine-B and bromamine-B in alkaline medium.

Materials and Methods

Chloramine-B (CAB, sodium N-chlorobenzenesulphonamide) and bromamine-B (BAB, sodium N-bromobenzenesulphonamide) were prepared in the laboratory and then the purity was checked by (i) iodometric estimation of active halogen present in them and (ii) their infrared and fourier transform ¹H and ¹³C NMR spectra. Aqueous stock solutions of the oxidants (0.1 mol dm⁻³) were prepared, standardised and stored in dark coloured bottles. Potassium thiocyanate (Merck, AR) was dried at 150°C and its purity checked by argentometric method¹⁰. All other reagents employed were of accepted grades of purity. The ionic strength of the medium was maintained at 0.5 mol dm⁻³ by adding concentrated solution of sodium perchlorate.

Stoichiometry and product analysis

The stoichiometries of CAB and BAB reactions with NCS⁻ were determined at different [OH⁻] (0.01 to 0.1 mol dm⁻³) by thermally equilibrating solutions containing NCS⁻ and oxidant in different ratios at 303 K for 24 hr. The cyanate and sulphate ions among the reaction products were detected by standard tests¹¹. Benzenesulphonamide (BSA), the reduced product of the oxidants was detected by TLC using ether-chloroform-n-butanol (2:2:1, v/v) as the solvent with iodine as the detecting reagent (RF = 0.88). Further the sulphate was quantitatively estimated by standard method¹⁰. The stoichiometry observed may be represented by Eq. (1).

NCS⁻ + 4 (RNCl⁻/RNBr⁻)Na⁺ + 2OH⁻ + 3H₂O →
4RNH₂ + SO₄²⁻ + (CNO⁻)⁻ + 4Na⁺ + 4Br⁻ /Cl⁻

where R = C₆H₅SO₂.

Results

Kinetics of reactions were studied over a wide range of [NCS⁻] (0.002-2.0 mol dm⁻³) at different [OH⁻] (Tables 1-3) and the orders in [NCS⁻] and [OH⁻] were determined from the log-log plots of kobs and [NCS⁻] or [OH⁻].

(a) Oxidation by chloramine-B

The concentration of CAB was varied at three initial [NCS⁻] (0.01, 0.1 and 0.5 mol dm⁻³). The plots of log ([CAB]/[CAB]) versus time were linear at least up to 75% completion of the reaction in all the cases except at low [NCS⁻] under the condition [NCS⁻] ≈ [OH⁻]. The rates were unaffected by change in [CAB] except under the condition when [NCS⁻] ≈ [OH⁻], suggesting the order to be unity in [CAB] over the entire range of [NCS⁻] (0.002-2.0 mol dm⁻³). The rate increased with increase in [NCS⁻] (Table 1) with fractional order dependence. The magnitude of fractional order in [NCS⁻] (Table 4) decreased further with increase in [NCS⁻]. The rate decreased with increase in [OH⁻] (0.001-0.5 mol dm⁻³) with fractional order in [OH⁻] in all the cases. pH of the reaction mixtures were measured as [CAB], [NCS⁻] and [OH⁻] were varied (Tables 1 and 2). The pH of the reaction mixtures changed only when [OH⁻] wav

The rates remained unaffected by the addition of the reaction products, BSA and Cl⁻ at both low and high [NCS⁻]. Variations of ionic strength of the medium had little effect on the rate.

(b) Oxidation by bromamine-B

Although the kinetic order in [BAB] was dependent on [NCS⁻] no definite kinetics could be established at low [NCS⁻] (0.01 mol dm⁻³). At this concentration log ([BAB]₀/[BAB]) versus time plots were linear but the rate varied with the change in [BAB].

At high [NCS⁻] (~0.03-0.5 mol dm⁻³) first order plots were linear at least upto 75% completion of the reaction. The pseudo-first order rate constants increased with increase in [OH⁻] (Table 3) indicating a fractional order of about 0.8 in [OH⁻]. But the rate was unaffected by the change in [NCS⁻] in the range of 0.025-0.5 mol dm⁻³. The rate increased slightly with increase in ionic strength of the medium. Rate constant at µ = 0.105, 0.5 and 1.0 mol dm⁻³ were 11.8, 12.7 and 13.2 x 10⁻⁴s⁻¹, respectively. Addition of the reaction products, BSA and Br⁻ had no effect on the rate.

Dependence of rate on dielectric constant

The rates increased with decrease in dielectric constant of the medium by changing the solvent composition by adding methanol. The true effect of the dielectric constant of the medium was determined by varying [NCS⁻] at different solvent compositions and constants of the rate limiting steps were calculated at each dielectric constant (Table 5) as described under discussion. The plots of logarithm of these constants versus 1/D plots were linear with positive slopes in both the cases.

The substrate concentration was also varied at different temperatures with both the oxidants and constants of the rate-limiting steps were calculated as functions of temperature. These constants were used to compute the activation parameters in both the cases (Table 4).

Discussion

Both chloramine-B and bromamine-B are fairly strong electrolytes in aqueous solutions. The following equilibria exist in their solutions:

\[
\text{RNXNa} \rightleftharpoons \text{RNX}^- + \text{Na}^+ \quad \text{(where X = Cl or Br)} \quad (2)
\]

\[
\text{RNX}^- + \text{H}^+ \rightleftharpoons \text{RNHX} \quad (\rho K_a \text{ of RNHBr} = 4.95 \text{ at } 25^\circ\text{C}) \quad (3)
\]

\[
\text{K_d} \quad \text{RNHX} \rightleftharpoons \text{RNX}_2 + \text{RNH}_2 \quad (4)
\]

\[
\text{K_d} \text{ for RNHBr} = 0.113 \text{ at } 25^\circ\text{C} \quad (4)
\]

\[
\text{K_b} \quad \text{RNHX} + \text{H}_2\text{O} \rightleftharpoons \text{HOX} + \text{RNH}_2 \quad (5)
\]

\[
\text{K_b} \text{ for RNHBr} = 4.2 \times 10^{-3} \quad (5)
\]

\[
\text{HOX} \rightleftharpoons \text{OX}^- + \text{H}^+ \quad (6)
\]

\[
[\text{K_e} = 3.3 \times 10^{-8} (\text{HOCl}) ; 2 \times 10^{-9} (\text{HOBr}) \text{ at } 25^\circ\text{C}]}
\]

Hence the probable reactive species in the alkaline solutions of CAB and BAB, depending upon the pH of the medium are RNHX, RNX⁻, HOX and OX⁻. X being Cl or Br. After pH 3 [RNX⁻] > [RNHX] and
upto pH 10 [RNHX] > [HOX], and thereafter [HOX] > [RNHX]. Above pH 9 [OX -] > [RNHX] or [HOX].

Mechanism of oxidations: (1) With chloramine-B—In the oxidation of NCS - by CAB first order in [CAB]o, fractional order in [NCS -] and inverse fractional order in [OH -] may be explained by Scheme 1,

\[
\begin{align*}
K_1 & \quad \text{OCl}^- + \text{NCS}^- + \text{H}_2\text{O} \rightleftharpoons \text{X} + \text{OH}^- \quad \text{(fast)} \\
K_2 & \quad \text{X} \rightarrow \text{NCSCl} + \text{OH}^- \quad \text{(slow)} \\
\text{NCSCl} + \text{OCl}^- + \text{H}_2\text{O} & \rightarrow \text{products} \\
\text{Scheme 1}
\end{align*}
\]

Based on Scheme 1, the rate law is given by Eq. (7)

\[
\frac{-d[CAB]}{dt} = \frac{K_1k_2[CAB][NCS^-][\text{H}_2\text{O}]}{[\text{OH}^-] + K_1[NCS^-][\text{H}_2\text{O}]}
\]

or

\[
k_{\text{obs}} = \frac{K_1k_2[NCS^-][\text{H}_2\text{O}]}{[\text{OH}^-] + K_1[NCS^-][\text{H}_2\text{O}]}
\]

... (7)

Fig. 1—(A) Plot of \(1/k_{\text{obs}}\) versus \([\text{OH}^-]\) (1) \(10^{-3}\) [CAB] = 0.5 mol dm \(^{-3}\); 10\([\text{NCS}^-]\) = 0.1 mol dm \(^{-3}\); \(T = 313\) K. (2) \(10^{-2}\) [CAB] = 1.0 mol dm \(^{-3}\); 10\([\text{NCS}^-]\) = 1.0 mol dm \(^{-3}\); \(T = 313\) K. (3) \(10^{-1}\) [CAB] = 5.0 mol dm \(^{-3}\); 10\([\text{NCS}^-]\) = 5.0 mol dm \(^{-3}\); \(T = 303\) K.

The plots of \(1/k_{\text{obs}}\) versus \([\text{OH}^-]\) (Fig. 1) and \(1/k_{\text{obs}}\) versus \([\text{NCS}^-]\) (Fig. 1) were linear with the same intercept in accordance with the rate law (8). The equilibrium constant \((K_1)\) and the disproportionation constant \((k_2)\) have been computed from the slope and intercepts of the plots \((K_1 = 1.09 \times 10^{-3}, k_2 = 2.04 \times 10^{-3}\) s \(^{-1}\) at higher [substrate]).

(2) With bromamine-B

Scheme 2 and rate law (9) account for the observed results of first order in [BAB], fractional order in [OH -] and zero order in [NCS -].

\[
\begin{align*}
K_4 & \quad \text{RNBr}^- + \text{OH}^- \rightleftharpoons \text{RNH}^- \quad \text{(fast)} \\
K_5 & \quad \text{X} \rightarrow \text{OBr}^- + \text{RNH}^- \quad \text{(slow)} \\
\text{OBr}^- + \text{NCS}^- + \text{H}_2\text{O} & \rightarrow \text{products} \\
\text{RNH}^- + \text{H}_2\text{O} & \rightarrow \text{RNH}_2 + \text{OH}^- \quad \text{(fast)} \\
\text{Scheme 2}
\end{align*}
\]

\[
\frac{-d[BAB]}{dt} = \frac{K_4k_5[BAB][\text{OH}^-]}{1 + K_4[\text{OH}^-]}
\]

or

\[
k_{\text{obs}} = \frac{K_4k_5[\text{OH}^-]}{1 + K_4[\text{OH}^-]}
\]

... (9)

1\/[k_{\text{obs}}] versus \([\text{OH}^-]\) (Fig. 2) was linear in conformity with rate law (11). The slope and intercept gave the formation constant \(K_4\) and decomposition constant \(k_5\) \((K_4 = 4.41; k_5 = 0.01\) s \(^{-1}\)).

The observed increase in rate with decrease in dielectric constant of the medium can be accounted by Laidler and Eyring equation\(^{14,15}\)

\[
\frac{1}{k_{\text{obs}}} = \frac{1}{K_4k_5[\text{OH}^-]} + \frac{1}{k_5}
\]

... (11)
\[ \ln k = \ln k_0 + \frac{e^2}{2DKT} \left( \frac{1}{r} - \frac{1}{r^*} \right) \] ... (12)

where \( k \)'s are the rate constants and \( r \)'s the radii of the reactant species and activated complex. It is evident from Eq. (12) that the rate is greater in a medium of lower dielectric constant when \( r^* > r \). In the present investigations, it is quite likely that the radius of the activated complex is greater than the radii of reactants as the rate determining step involves the interaction between negative ions.

It can be concluded from the examination of kinetic data and above discussion that BAB is more powerful oxidant than CAB in the alkaline medium.
